Practical Application of Refrigerants R 600a and R 290 in Small Hermetic Systems
Refrigerant R 600a – isobutane and R 290 – propane are possible replacements for other refrigerants, which have high impact on environment, in small hermetic systems, like factory made household and commercial refrigerators and freezers. They have zero ozone depletion potential ODP and a negligible global warming potential GWP. Furthermore they are part of petrol gases from natural sources.

The refrigerant R 600a has been in use in the past, in refrigerators up to the 40'es, and has now again found a wide use in domestic refrigerators and freezers in Europe, where most refrigerators today are manufactured using R 600a as refrigerant.

Isobutane R 600a is a well suited refrigerant for household application, with good energy efficiency, but with a very different characteristic in several points, which implies the design to be made or adopted.

The refrigerant R 290 has been in use in refrigeration plants in the past, and is still used in some industrial plants. In domestic heat pumps and air conditioners R 290 has been used in Germany and Sweden for some years, however, with different level of success.

Because of the availability of isobutane and propane all over the world they have been discussed widely for CFC, H-CFC and HFC replacement.

Isobutane R 600a and Propane R 290 are possible refrigerants for these applications, with good energy efficiency, but special care has to be taken to the flammability.

## 1 Refrigerant

The properties of R 600a and R 290 differ from other refrigerants commonly used in small hermetic systems, as shown in table 1. This leads to a different design of details in many cases.

</table>
1.1 Pressure R 600a

The first remarkably large difference between R 600a and R 134a or R 12, is found in the pressure level, which is much lower, e.g. at -25 °C evaporation roughly 55 % of R 134a or 45 % of R 12. In connection with this the normal boiling point is a 15 K resp. 18 K higher. This leads to operating pressures being very much lower than previously common. Evaporators of household refrigerators will thus operate below normal atmospheric pressure.

![Figure 1: Vapour pressure of different refrigerants versus temperature](image)

The low pressure level is connected to a relatively high critical temperature. This gives a good cooling capacity even at high condensing temperature.

1.2 Capacity R 600a

R 600a has roughly 50 % of R 12 or 55 % of R 134a volumetric capacity at 55 °C condensing temperature, as seen in figure 2. Because of this the necessary compressor swept volume will be up to 2 times the swept volume used for R 12.

The volumetric cooling capacity is a value calculated from suction gas density and enthalpy difference of evaporation. The compressor capacity characteristics, in terms of capacity over evaporating temperature, are close to those of the other refrigerants, as shown in figure 3.
**Figure 2:** Volumetric capacity of R 600a and R 134a, relative to R 12, over evaporation temperature, at 55 °C condensing and 32 °C suction gas temperature.

**Figure 3:** Cooling capacity versus evaporating temperature with different refrigerants.
1.3 Pressure R 290

A difference between R 290 and R 134a is found in the pressure level, which is closer to R 22 and R 404A, e.g. at -25 °C evaporation the pressure is roughly 190 % of R 134a, 81 % of R 404A, 350% of R 600a or almost exactly that of R 22. In connection with this the normal boiling point is close to R 22 also. Evaporators will thus have to be designed similar as for R 22 or R 404A.

Figure 4: Vapour pressure of different refrigerants versus temperature

The pressure level and critical temperature are almost like R 22. However, the discharge temperature is much lower. This gives the opportunity to work at higher pressure ratios, means lower evaporating temperatures, or at higher suction gas temperatures.

1.4 Capacity R 290

R 290 has roughly 90 % of R 22 or 150 % of R 134a volumetric capacity at 45 °C condensing temperature, as seen in figure 5. Because of this the necessary compressor swept volume is close to R 22 also, and 10 % to 20 % larger than for R 404A. The volumetric capacity is approx. 2.5 to 3 times that of R 600a. Thus the choice for either R 290 or R 600a will lead to differences in system design because of very different necessary volume flow for same refrigeration need.

The volumetric cooling capacity is a value calculated from suction gas density and enthalpy difference of evaporation.
1.5 Refrigerant charge

If R 600a or R 290 would be charged into an unchanged refrigeration system, charge amount counted in grams would be much lower. However, calculated in cm³, the charge would be roughly the same liquid volume in the system. This gives charges of approx. 40-45 % of R 22, R 12, R 134a or R 404A charge in grams, according to the data from table 1, which also corresponds with empirical values. Maximum charge according to safety regulations is 150 g for household and commercial refrigerated appliances and similar applications, which corresponds to approx. 360 g of usual refrigerants. Additionally experience has shown a higher sensitivity of the systems to charge deviations for R 600a. Especially undercharging tends to give higher energy consumption. This means that charging accuracy has to improve, in cm³ and even more in grams. On charges of approx. 20 g, which are found on small larder refrigerators, accuracy has to be within 1 g.

1.6 Purity

Specification for hydrocarbon refrigerants like R 600a and R 290 is not found in international standards. Some data are enclosed in the German standard DIN 8960 of 1998, which is an extended version of ISO 916. The purity of the refrigerant has to be judged from chemical and stability side, for compressor and system lifetime, and from thermodynamic side regarding refrigeration system behaviour and controllability.

The specification in DIN 8960 is a safe general hydrocarbons refrigerant specification, adopted from other refrigerants criteria catalogue and covering propane, isobutane, normal butane, and others. Some points can possibly be accepted a little less narrow for specific refrigerants and impurities combinations after extensive evaluation.

For the time being no refrigerant quality according to an official standard is on the market. The specifications of possible qualities have to be checked with the supplier in details.

Figure 5: Volumetric capacity of R 290, R 134a, R 404A and R 600a, relative to R 22, over evaporation temperature, at 45 °C condensing and 32 °C suction gas temperature, no subcooling.
Liquified petrol gas LPG for fuel applications or technical grade 95% purity is not sufficient for hermetic refrigeration. Water, sulfur and reactive compounds contents has to be on a lower level than guaranteed for those products. Technical grade 99.5%, also called 2.5, is widely used.

1) This content is not explicitly stated in DIN 8960. Only the impurities are listed and limited. The main content is the rest up to 100%.

From thermodynamic calculation an isomer content of R 600 normal Butane up to 5% in R 600a isobutane is not critical and still does not exceed the temperature glide criteria and has only very low impact on pressure, less than 0.2 K temperature at evaporation.

2) From compressor point of view a content up to approx. 1% of butane in R 290 or 1% of propane in R 600a is acceptable.

3) This is a maximum value for every single substance of the multiple unsaturated hydrocarbons.

4) This is a maximum value for every single aromatic compound.

5) This is a preliminary value, to be reviewed with growing experience.

2 Materials

Refrigerant R 600a is mostly used with mineral compressor oils, so material compatibility is almost identical to R 12 situation from oil side. Use of alkyl benzenes or polyolester oil is also possible.

Refrigerant R 290 is used with polyolester oil in Danfoss compressors, so material compatibility is almost identical to R 134a or R 404A situation from oil side.

R 600a and R 290 are chemically inactive in refrigeration circuits, so no specific problems should occur there. Solubility with the oil is good. Direct material compatibility is less problematic. On some rubbers, plastics and especially chlorinated plastics however, problems have been observed, but these materials are normally not present in small hermetic systems. Some materials, on which problems have been reported by different testers, are listed in the table 3. On critical materials test have to be performed for the specified use.

### 2.1 Driers

For domestic and commercial refrigerators, the common desiccant is a molecular sieve, a zeolithe. For R 290 a material with 3 Å pores is recommended, like for R 134a and R 404A, e.g. UOP XH 7, XH 9 or XH 11, Grace 594, CECA Siliporite H3R. Pencil driers for R 134a can be used without changes normally. Burst pressure demands of IEC/EN resp. UL 60335 have to be complied with. See also note CN.86.A.

If hardcore driers are to be used, please ask the manufacturer for compatibility to R 600a or R 290. Danfoss type DCLE driers can be used.

### 3 Flammability and safety

The main disadvantage discussed in connection with R 600a and R 290 use is the risk based in its flammability. This leads to necessity for very careful handling and safety precautions.

#### Table 4: Flammability of isobutane and propane

<table>
<thead>
<tr>

<td>470 °C</td>
</tr>
</tbody>
</table>

Because of the flammability in a wide concentration range safety precautions are necessary, on the appliance itself and in the manufacturing factory. The risk assessments behind these two situations are quite different. Main common starting point is, that accidents need to have two essential preconditions. One is the flammable mixture of gas and air and the other is the ignition source of a certain energy level or temperature. These two have to be present together for combustions, so avoidance of this combination has to be proven.

![Figure 6: Yellow warning labels](image)

Danfoss compressors for R 600a and R 290 have internal protectors and PTC starters or special relays, both preventing from sparks coming out near the compressor, because it can not be guaranteed to hold surrounding air below LEL in case of leaks close to the compressor.

They are equipped with a yellow label warning for flammable gas, like shown in figure 6.
3.1 Appliance

For safety testing of household refrigerators and similar applications international standards have been established. The rules are included in the latest versions (edition 4, resp. amendments to edition 3) of:

- IEC / EN 60335-2-24 for household refrigerators and freezers
- IEC / EN 60335-2-89 for commercial refrigerated appliances
- IEC / EN 60335-2-34 for motorcompressors

and for North America:

- UL 60335-2-24 and UL 250 for household refrigerators and freezers
- UL 471 Amendment SB for commercial refrigerated appliances
- UL 60335-2-34 for motorcompressors

which are the normal electrical safety standards. Approvals of refrigerated appliances using hydrocarbons as refrigerant are done according to the procedures of these standards in Europe since 1994. The methodology is base for the following short description. Other applications have to take different national standards and legislation into account, e.g. EN 378, DIN 7003, BS 4344, SN 253 130, which can have different demands.

- All electrical elements switching during normal operation are taken to be possible ignition sources. This includes thermostat, door contacts for lighting, on/off and other switches, like superfrost, compressor relays, external klixon and other overload or safety switches, defrost timers and so on.
- All refrigerant containing parts are taken to be possible refrigerant sources through leaks. This includes evaporators, condensers, door heaters, tubings and the compressor.
- Maximum refrigerant charge is set to be 150 g for most of these standards, please see the specific standard for reference. By keeping the charge to max. 20 % of lower explosion level LEL, which is approx. 8 g/m³, for a standard kitchen, ignition risk is very low, even if refrigerant distribution in case of leakage is uneven for some time first.

The main target of the safety precautions is to separate rooms with refrigerant containing parts from rooms with switching elements.

![Figure 7: Appliance designs variants](image)

In figure 7 three principal possibilities are shown.
Option 1 has evaporator and thermostat/door switch located in the storage volume both. This is critical for flammable refrigerants and should not be used. Option 2 has evaporator inside and thermostat/door switch outside on top. This normally gives a safe solution. Option 3 has thermostat/door switch inside, but evaporator foamed in place behind the inner liner. This is a possible solution used in many cases. Chosen option has to be designed and proven in leakage test according to IEC / EN 60335 resp. UL demands.

On many refrigerator or freezer designs this separation is already the existing situation. • Large free standing bottle coolers and freezers often have all electrical switches in the top panel • Some refrigerators have the evaporators hidden behind the liner, in the foam, means not in the cabinet space where thermostats and so on are allowed in this case.

Critical situation is given whenever it is not possible to avoid evaporator and thermostat or switches being in the cabinet (Option 1). In this case two possibilities are left. • Thermostats and switches have to be changed to sealed versions preventing gas from penetrating them and thus reaching the switching contacts. Danfoss offers electromechanical thermostats with sealed switches (077B with enclosed break device EBD) and electronic thermostats (ETC) suitable for this application. • Fans inside the refrigerated compartment have to be safe and sparkfree even if blocked. • Electrical connectors and lamp holders have to be proven according to certain specifications.

Every R 600a and R 290 appliance type has to be tested and approved according to the IEC / EN procedures, by an independent institute, even if all above mentioned criteria are included in the design. Please see the standard for details. Instructions for use should contain some informations and warnings for careful handling, like not to defrost freezer compartments with knives, and for installing in a room with at least 1 m³ of space per 8 g of charge, the latter to be seen on the type label.

Systems using relays or other electrical components near the compressor must meet the specifications. These are including • Fans at the condenser or compressor must be sparkfree even when blocked or overloaded. Either they have to be designed not to need a thermal switch, or this switch has to meet IEC 60079-15. • Relays have to meet IEC 60079-15 or being placed where a leakage can not produce a flammable mixture with air, e.g. in a sealed box or at high altitude.

3.2 Factory

The refrigerant containing system and the safety system design is to be approved and controlled regularly by local authorities normally. Below the design principles for installations in Germany are given. In many details this is based on regulations for liquified gas installations. Specialities are found around the charging stations, where gas connectors are to be handled frequently and a charging of the appliances occurs.

The basic principles for safety are • Forced ventilation to avoid local accumulation of gas. • Standard electrical equipment except for the ventilation fans and safety systems. • Gas sensors continuously monitoring in possible leakage areas like around charging stations, with alarm and doubling of ventilation at 15 % to 20 % of LEL and with disconnection of all non explosion proof electrics in the monitored area at 30 % to 35 % of LEL, leaving the fans running at full speed. • Leakage test on appliances before charging to avoid charging of leaking systems. • Charging stations designed for flammable refrigerants and connected to the safety systems.
Safety system design can be supported by suppliers of charging stations and gas sensing equipment in many cases.

For handling of R 600a or R 290 in small containers, the rules are less strict in some countries.

### 4 Refrigeration system design

In many cases of transition from non-flammable to flammable refrigerants, the appliance cabinet has to be modified for safety reasons as listed in section 3.1. But changes can additionally be necessary for other reasons.

Refrigerant containing system parts have according to IEC / EN 60335 to withstand a specified pressure without leaking. High pressure side has to withstand saturation overpressure of 70 °C times 3.5, low pressure side has to withstand saturation overpressure of 20 °C times 5. This gives the following values:

<table>
<thead>
<tr>
<th></th>
<th>R 600a</th>
<th>R 290a</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low Pressure side</td>
<td>25</td>
<td>38</td>
</tr>
<tr>
<td>High Pressure side</td>
<td>35</td>
<td>90</td>
</tr>
</tbody>
</table>

National standards and UL standards might have different specifications, depending on the application.

#### 4.1 Heat exchangers

The refrigeration system efficiency will normally not cause a need for changing evaporator or condenser size, means outer surface can be left the same as with R 134a, R 22 or R 404A. Inside design of the evaporator possibly needs some modification, because the refrigerant volume flow is different, according to the compressor swept volume. With R 290 it is close to R 22 or R 404A.

With R 600a compared to R 12 or R 134a the refrigerant volume flow increases by 50% to 100% according to the larger compressor swept volume. This leads to increased pressure drop in the refrigerant channels or tubes, if the cross flow section stays the same.

To keep the refrigerant flow speed within the recommended range of 3 to 5 m/s it may be necessary to make the cross flow sections wider. In rollbond evaporators for R 600a this can be done by either increasing channel system height, e.g. from 1.6 mm to 2 mm, or by designing parallel channels instead of single ones. A parallel channel design however has to be developed very careful to avoid liquid accumulations.

Aluminium rollbond evaporators can normally not be used for R 290 because of the high demands on burst pressure.

Special care has to be taken when designing the accumulator in the system. When using R 22, R 12, R 404A or R 134a the refrigerant is heavier than the oil used, while with R 600a and R 290 the refrigerant is less heavy, as can be seen in the data table 1. This can lead to oil accumulation if the accumulator is too large, especially too high, and has a flow path which does not guarantee emptying sufficiently during startup phase of the system.

Evaporator design hints can be found in note CN.82.A.
For R 600a experience and theoretical modellings show the need for a flow rate almost similar to R 12 again. When changing a refrigeration system with capillary from R 12 to R 134a, very often the capillary flow rate, expressed in litres of nitrogen per minute at specific conditions, was reduced by elongating the capillary, or by taking a smaller inner diameter.

For R 290 experience shows the need for a capillary flow rate almost similar to R 404A. At least this is a good starting point for optimization.

As with R 134a and R 404A for R 600a and R 290 the suction line heat exchanger is very important for system energy efficiency of R 290, which it was not for R 22, see figure 8. The figure shows increase of COP with superheat from few K up to +32 °C return gas temperature, where a range from +20 °C to approx. +32 °C is usual for small hermetic systems. This large increase in COP for R 290 is caused by a high vapour heat capacity. In combination with the need for keeping the refrigerant charge close to maximum possible in the system, thus giving no superheat at evaporator outlet, the suction line heat exchanger has to be very efficient for preventing air humidity condensation on the suction tube. In many cases an elongation of the suction line and capillary gives efficiency improvements. The capillary itself has to be in good heat exchanging contact with the suction line for as long a part of total length as possible.

![Figure 8: Theoretical COP increase of different refrigerants versus suction temperature with adiabatic compression, internal heat exchange, at -25 °C evaporation, 45 °C condensation, no subcooling before internal heat exchanger](attachment:image.jpg)

At high superheat, with good internal heat exchange, the theoretical COP of R 290, R 600a and R 134a is higher than for R 22. At very low superheat the COP of R 290, R 600a and R 134a is lower than for R 22. The R 290 behaviour is similar to R 134a, with respect to internal heat exchange.
4.3 Evacuation

For R 290 generally the same rules for evacuation and processing are valid as for R 22, R 134a or R 404A systems. The maximum allowable content of non-condensable gases is 1%.

For R 600a the evacuation process mostly has to be improved remarkably. At -25 °C evaporation temperature R 600a has a pressure of 0.58 bar, while R 12 has 1.24 bar and R 134a has 1.07 bar, which means only 47% or 54%, or roughly half, of previously handled pressure values are present.

This means that non-condensable gases contents in a refrigeration system will have double the negative effect than with the other two refrigerants, or, taken from that, necessary maximum level for non-condensable gases residue has to be halved. Because of a main part of non-condensable gases coming from the compressor oil, which takes some time to extract and shows to be an effect not linear with time, minimum necessary evacuation times will be more than double.

Working with single side evacuation on the process tube of the compressor only, necessary evacuation times will raise, depending on the appliance design. Changing to two side evacuation, on process tube and a second connection at the drier, reduces necessary time again, but increases cost.

Too high level of non-condensable gases increases energy consumption because of higher condensing temperature and a portion of the transported gas being inactive. It can additionally increase flow noise. On two temperature one compressor systems it can give problems with the cyclic defrosting of the refrigerator cabinet, where risk for ice block forming is increased.

4.4 Noise

While the compressors tend to be less noisy with R 600a at low cooling capacity, compared to R 134a, partly because of the lower working pressure levels, some other noise problems can occur on appliances.

The larger required displacement can cause higher vibration and thus create noise in the appliance. The increased volume flow can give higher flow noise in evaporators, especially at the injection point. But even if this noise in many cases is not increased, it can be a problem.

If compressor noise is reduced, the flow noise appears to be the loudest part, not covered by the compressor noise any longer, and it is an unexpected noise, a hiss. Additionally the higher volume flow can result in higher gas pulsations and that by increase flow noise or even create vibrations on appliance parts.

Increased suction line heat exchanger length can reduce flow noise too, because it equalizes the flow and thus stabilizes injection.

4.5 Cleanliness of components

The specifications for cleanliness are generally comparable to R 134a or R 404A. The only official standard on cleanliness of components for refrigeration use is the DIN 8964, which also is used in several countries outside Germany. It specifies maximum contents of soluble, insoluble and other residues. The methods for determining soluble and insoluble contents are to be modified for the actual refrigerant R 600a and R 290, but in principle the same limits are useful.

5. Service

Servicing and repair of R 600a and R 290 systems is possible for skilled and well trained service technicians. Please see note CN.73.C for details. Local laws and regulations have to be taken into account also. It needs very careful handling because of the flammability of the gas, which is a potential danger during work on the refrigeration system. A good ventilation of the room is necessary and the discharge of the vacuum pump has to be lead to open air. The equipment of the service technician has to meet the requirements of R 600a and R 290 in terms of evacuation quality and refrigerant charge accuracy. An electronic scales is recommended to control refrigerant charge to within the needed accuracy.
Conversion of a R 22, R 12, R 502 or R 134a system to R 600a or R 290 is not recommended by Danfoss, because these systems are not approved for flammable refrigerant use, so electrical safety is not proven to be according to the needed standards.
